BETA AMYLOID DEPOSITS AND HYPERPHOSPHORYLATION OF TAU IN THE PANCREAS IN TYPE 2 DIABETES

Judith Miklossy

Vancouver, BC, Canada
INTRODUCTION

Strong epidemiologic evidence shows an association between Alzheimer disease (AD) and type 2 diabetes.

These age related chronic disorders share several risk factors.

Both are associated with Down syndrome.

Amyloid formation is a key player in the pathogenesis of both.
INTRODUCTION

Alzheimer’s disease:

4kDa Aβ accumulates in senile plaques which is derived from a 120 kDa AβPP

Hyperphosphorylated tau is the major component of the paired helical filament in neurofibrillary tangles
INTRODUCTION

Type 2 diabetes:

Islet amyloid polypeptide (IAPP) amylin aggregates and accumulates in the Langerhans islets of the pancreas. It derives from a larger 89-amino acid precursor protein called proamylin.

Islet β-cells produce both insulin and amylin and the degeneration of these cells will lead to decreased insulin and amylin deposits. Cooper, 1987; Sanke, 1988.

More than 80% of all diabetic patients: type 2 diabetes.
Aβ IN ISLET AMYLOID DEPOSITS

The pathogenesis of amyloid formation in AD and type 2 diabetes is still remains unclear.

Aβ and amylin aggregates are toxic to neurons and islet cells.

Aβ deposition in non-neuronal tissues was previously observed

*Joachim, 1989, Askanas, 1994, Dentchev et al.; 2003; Goldstein et al., 2003*

Pathological fibrillary lesions similar to paired helical filaments were also observed in various other organs than the brain, including the pancreas *Miklossy et al. JNEN, 1999*

Whether Aβ and phosphorylated tau may be associated with islet amyloid deposits in type-2 diabetes is not known.
Aβ IN ISLET AMYLOID DEPOSITS

Pancreas tissue of 36 autopsy cases was analyzed
20 AD, and 16 controls
10 clinically and pathologically confirmed
type 2 diabetes

Ten anti-Aβ antibodies which recognized several epitopes, including Aβ
8-17 (6F/3D), Aβ17-24 (4G8), Aβ17-28 (2F9AF), Aβ40 (QCB1-40) and
Aβ42 (QCB1-42, 21F12).

Five antibodies raised against tau protein, including AT8 and anti-
\[ p(409)\text{Ser} \]

Ubiquitin. Apo-E, Apo-a, IB1, JNK

Two rabbit anti- human IAPP 1-37 (amylin) and a monoclonal antibody to
aa. 29-37 synthesized peptide of human amylin were used

The role of local inflammatory processes in AD is well established (McGeer, 2002; McGeer and Rogers, 1992).

Systemic indicators of inflammation have also been documented in type 2 diabetes (Kolb, 2005; Schmidt, 1999). Whether local inflammatory processes may also be present in the pancreas in type 2 diabetes is not known.

7 autopsy cases: 5 type 2 diabetes and 2 controls

Anti-HLA-DR, DP, DQ (CR3/43) marker of activated macrophages.

Monoclonal antibodies directed against human complement proteins C3d, C4d and C5b9 (terminal attack complex) which detect bacteria marked for destruction.

CD20, CD4 and CD8 antibodies to detect B, T4 and T8 lymphocytes.
CHRONIC INFLAMMATION

Insulin, IGF-1 and LPS influence AβPP level in non neuronal cells

Western blot analysis was performed to analyze whether LPS, insulin and IGF-1 may also affect AβPP levels in non neuronal cells (U87MG, TE671, fibroblasts).

The effect of IGF-1 on AβPP was also analyzed in fibroblast cell lines (R-, R503, R600) expressing different levels of IGF-1 receptor.
CONCLUSION

A host reaction similar to AD is also key player in the pathogenesis of type 2 diabetes.

Local inflammatory processes, including complement activation, are also involved in the pathogenesis of type 2 diabetes.

The results also suggest that bacteria or their persistent debris may induce and sustain chronic inflammation and amyloid deposition in type 2 diabetes.

Further investigations are needed as a parallel antibacterial and antiinflammatory therapy may prevent or stop the degenerative process.
